Statistical Natural Language Processing Classification

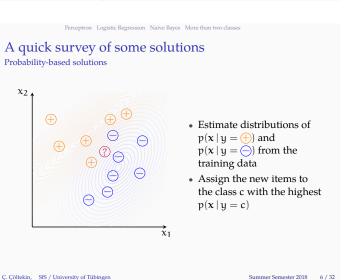

Çağrı Çöltekin

University of Tübingen Seminar für Sprachwissenschaft

Summer Semester 2018

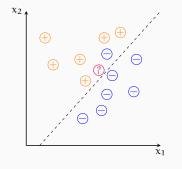

When/why do we do classification

- Is a given email spam or not?
- What is the gender of the author of a document?
- Is a product review positive or negative?
- Who is the author of a document?
- What is the subject of an article?

As opposed to regression the outcome is a 'category'.

A quick survey of some solutions

(Linear) discriminant functions

- Find a discriminant function (f) that separates the training instance best (for a definition of 'best')
- Use the discriminant to predict the label of unknown instances

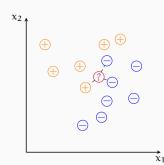

$$\hat{y} = \begin{cases} + & f(x) > 0 \\ - & f(x) < 0 \end{cases}$$

Ç. Çöltekin, SfS / University of Tübing

Perceptron Logistic Regression Naive Bayes More than two cl

A quick survey of some solutions

Instance/memory based methods

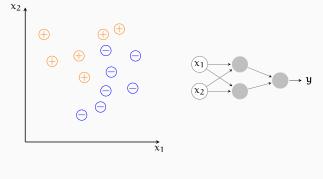

- No training: just memorize the instances
- During test time, decide based on the k nearest neighbors
- $\bullet\,$ Like decision trees, kNN is non-linear
- It can also be used for regression

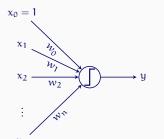

Ç. Çöltekin, SfS / University of Tübingen

C. Cöltekin, SfS / University of Tübingen

A quick survey of some solutions Artificial neural networks

The perceptron

$$y = f\left(\sum_{i}^{n} w_{i} x_{i}\right)$$

where

$$f(x) = \begin{cases} +1 & \text{if } \sum_{i=1}^{n} w_{i} x_{i} > 0\\ -1 & \text{otherwise} \end{cases}$$

Similar to the *intercept* in linear models, an additional input x_0 which is always set to one is often used (called bias in ANN literature.)

Ç. Çöltekin, SfS / University of Tübingen

Perceptron Logistic Regression Naive Bayes More than two classes

Learning with perceptron

- We do not update the parameters if classification is correct
- For misclassified examples, we try to minimize

$$E(w) = -\sum_{i} w x_{i} y_{i}$$

where i ranges over all misclassified examples

· Perceptron algorithm updates the weights such that

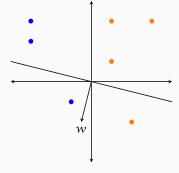

$$\begin{aligned} w \leftarrow w - \eta \nabla \mathsf{E}(w) \\ w \leftarrow w + \eta x_{\mathsf{i}} y_{\mathsf{i}} \end{aligned}$$

for a misclassified example ($\boldsymbol{\eta}$ is the learning rate)

Ç. Çöltekin, SfS / University of Tübingen

Perceptron Logistic Regression Naive Bayes More than two classes

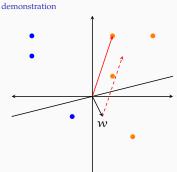

Perceptron algorithm (online) demonstration

- 1. Randomly initialize *w* the decision boundary is orthogonal to w
- 2. Pick a misclassified example x_i add $y_i x_i$ to w
- 3. Set $\mathbf{w} \leftarrow \mathbf{w} + y_i \mathbf{x}_i$, go to step 2 until convergence

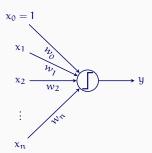

Perceptron Logistic Regression Naive Bayes More than two classes

Perceptron algorithm (online)

- 1. Randomly initialize w the decision boundary is orthogonal to w
- 2. Pick a misclassified example x_i add $y_i x_i$ to w
- 3. Set $\mathbf{w} \leftarrow \mathbf{w} + y_i \mathbf{x}_i$, go to step 2 until convergence

The perceptron: in plain words

- Sum all input x_i weighted with corresponding weight
- · Classify the input using a threshold function

positive the sum is larger than 0 negative otherwise

Perceptron Logistic Regression Naive Bayes More than two classes

The perceptron algorithm

- The perceptron algorithm can be online update weights for a single misclassified example batch updates weights for all misclassified examples at once
- The perceptron algorithm converges to the global minimum if the classes are linearly separable
- If the classes are not linearly separable, the perceptron algorithm will not stop
- We do not know whether the classes are linearly separable or not before the algorithm converges

Perceptron: a bit of history

- The perceptron was developed in late 1950's and early 1960's (Rosenblatt 1958)
- It caused excitement in many fields including computer science, artificial intelligence, cognitive science
- The excitement (and funding) died away in early 1970's (after the criticism by Minsky and Papert 1969)
- The main issue was the fact that the perceptron algorithm cannot handle problems that are not linearly separable

Ç. Çöltekin, SfS / University of Tübinger

Perceptron Logistic Regression Naive Bayes More than two classes

Why not linear regression?

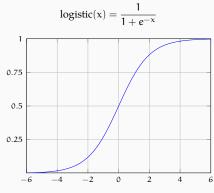

- What is P(y | x = 2)?
- Is RMS error appropriate?

Ç. Çöltekin, SfS / University of Tübin

Perceptron Logistic Regression Naive Bayes More than two cl

Logistic function

Ç. Çöltekin, SfS / University of Tübinger

Perceptron Logistic Regression Naive Bayes More than two class

How to fit a logistic regression model (2)

- Bad news: there is no analytic solution
- · Good news: the (negative) log likelihood is a convex function
- We can use iterative methods such as gradient descent to find parameters that maximize the (log) likelihood
- · Using gradient descent, we repeat

$$\mathbf{w} \leftarrow \mathbf{w} - \alpha \nabla J(\mathbf{w})$$

until convergence, α is called the *learning rate*

Logistic regression

- Logistic regression is a classification method
- In logistic regression, we fit a model that predicts $P(y \mid x)$
- Logistic regression is an extension of linear regression
 - it is a member of the family of models called generalized
- Typically formulated for binary classification, but it has a natural extension to multiple classes
- The multi-class logistic regression is often called maximum-entropy model (or max-ent) in the NLP literature

Perceptron Logistic Regression Naive Bayes More than two classes

Fixing the outcome: transforming the output variable

Instead of predicting the probability p, we predict logit(p)

$$\hat{y} = logit(p) = log \frac{p}{1 - p} = w_0 + w_1 x$$

- $\frac{p}{1-p}$ (odds) is bounded between 0 and ∞
- $\log \frac{p}{1-p}$ (log odds) is bounded between $-\infty$ and ∞
- we can estimate logit(p) with regression, and convert it to a probability using the inverse of logit

$$\hat{p} = \frac{e^{w_0 + w_1 x}}{1 + e^{w_0 + w_1 x}} = \frac{1}{1 + e^{-w_0 - w_1 x}}$$

which is called logistic function (or sometimes sigmoid function, with some ambiguity).

Ç. Çöltekin, SfS / University of Tübinge

on Logistic Regression Naive Bayes More than two cl

How to fit a logistic regression model

with maximum-likelihood estimation

$$P(y = 1 | \mathbf{x}) = p = \frac{1}{1 + e^{-wx}} \qquad P(y = 0 | \mathbf{x}) = 1 - p = \frac{e^{-wx}}{1 + e^{-wx}}$$

$$P(y = 0|x) = 1 - p = \frac{e^{-wx}}{1 + e^{-wx}}$$

The likelihood of the training set is,

$$\mathcal{L}(\mathbf{w}) = \prod_{i} p^{y_i} (1 - p)^{1 - y_i}$$

In practice, we maximize \log likelihood, or minimize $-\log$ likelihood:

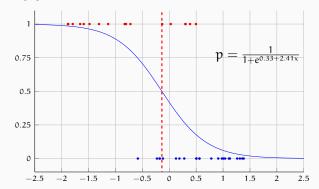

$$-\log \mathcal{L}(\textbf{\textit{w}}) = -\sum_{i} y_{i} \log p + (1-y_{i}) \log (1-p)$$

two predictors

Naive Bayes classifier

- Naive Bayes (NB) classifier is a well-known simple
- It was found to be effective on a number tasks, primarily in document classification
- Popularized by practical spam detection applications
- Naive part comes from the strong independent assumption
- Bayes part comes from use of Bayes' formula for inverting conditional probabilities
- · However, learning is (typically) 'not really' Bayesian

Ç. Çöltekin, SfS / University of Tübing

Perceptron Logistic Regression Naive Bayes More than two classes

Naive Bayes: estimation (cont.)

- $\bullet\,$ Class distribution, p(c), is estimated using the MLE on the training set
- With many features, $\textbf{x} = (x_1, x_2, \dots x_n)$, $p(\textbf{x} \,|\, c)$ is difficult to estimate
- Naive Bayes estimator makes a conditional independence assumption: given the class, we assume that the features are independent of each other

$$p(x \mid c) = p(x_1, x_2, ..., x_n \mid c) = \prod_{i=1}^{n} p(x_i \mid c)$$

Perceptron Logistic Regression Naive Bayes More than two class

a simple example: spam detection

Training set:

| document | label |
|--|-------------------------|
| w ₁ w ₂ w ₃ | w ₄ not spam |
| w ₁ w ₂ w ₅ | spam |
| $w_1 w_4 w_1$ | not spam |
| W3 W4 W5 | not spam |
| W2 W4 W5 | w ₆ spam |

Test on:

not spam W1 W4 W5

How about:

 $w_1 w_5 w_7$ not spam

Logistic regression as a generalized linear model

Short divergence to statistics

Logistic regression is a special case of generalized linear models (GLM). GLMs are expressed with,

$$g(y) = Xw + \epsilon$$

- \bullet The function g() is called the link function
- ullet is distributed according to a distribution from *exponential* family
- \bullet For logistic regression, g() is the logit function, ε is distributed binomially

Naive Bayes: estimation

- Given a set of features x, we want to know whether the class c of the object we want to classify
- During prediction time we pick the class, ĉ

$$\hat{c} = \arg\max_{c} P(c \,|\, x)$$

· Instead of directly estimating the conditional probability, we invert it using the Bayes' formula

$$\hat{c} = \operatorname*{arg\,max}_{c} \frac{p(\boldsymbol{x} \,|\, \boldsymbol{c}) p(\boldsymbol{c})}{p(\boldsymbol{x})} = \operatorname*{arg\,max}_{c} p(\boldsymbol{x} \,|\, \boldsymbol{c}) p(\boldsymbol{c})$$

• Now the task becomes estimating $p(x \mid c)$ and p(c)

Ç. Çöltekin, SfS / University of Tübing

Perceptron Logistic Regression Naive Bayes More than two classes

Naive Bayes: estimation (cont.)

- The probability distributions $p(x_i \,|\, c)$ and p(c) are typically estimated using MLE (count and divide)
- A smoothing technique may be used for unknown features (e.g., words)
- Note that $p(x_i | c)$ can be

binomial e.g, whether a word occurs in the document or not cagegorical e.g, estimated using relative frequency of words continious assuming the data is distributed according to a known distribution

Classifying classification methods

another short digression

- Some classification algorithms are non-probabilistic, discriminative: they return a label for a given input. Examples: perceptron, SVMs, decision trees
- · Some classification algorithms are discriminative, probabilistic: they estimate the conditional probability distribution $p(c \mid x)$ directly. Examples: logistic regression, (most) neural networks
- Some classification algorithms are generative: they estimate the joint distribution p(c, x). Examples: naive Bayes, Hidden Markov Models, (some) neural models

C. Cöltekin, SfS / University of Tübinger

More than two classes

- Some algorithms can naturally be extended to multiple
- Others tend to work well in binary classification
- Any binary classifier can be turned into a k-way classifier by

 - training k one-vs.-rest (OvR) or one-vs.-all (OvA) classifiers. Decisions are made based on the class with the highest confidence score.
 - This approach is feasible for classifiers that assign a weight or probability to the individual classes training $\frac{k(k-1)}{2}$ one-vs.-one (OvO) classifiers. Decisions are
 - made based on majority voting

C. Cöltekin, SfS / University of Tübingen

Perceptron Logistic Regression Naive Bayes More than two classes

Multi-class logistic regression

- Generalizing logistic regression to more than two classes is straightforward
- We estimate,

$$P(C_k \mid x) = \frac{e^{w_k x}}{\sum_j e^{w_j x}}$$

Where C_k is the k^{th} class. j iterates over all classes.

- The function is also known as the softmax function, used frequently in neural network models as well
- This model is also known as a log-linear model, Maximum entropy model, Boltzmann machine

Ç. Çöltekin, SfS / University of Tübingen

One vs. Rest

- For 3 classes we fit 3 classifiers separating one class from the rest
- Some regions of the feature space will be ambiguous
- We can assign labels based on probability or weight value, if classifier returns
- One-vs.-one and majority voting is another option

Ç. Çöltekin, SfS / University of Tübinger

Summary

- We discussed two basic classification techniques: perceptron, logistic regression, naive Bayes
- We left out many others: SVMs, decision trees, ...
- We will discuss some (non-linear) classification methods later

Wed practical session: solutions/discussion of assignment 1 Fri ML evaluation, quick summary so far Mon Break
